Examination, course FY8104 Symmetry in physics

Wednesday December 9, 2009

Time: 09.00–13.00

Grades made public: Wednesday December 30, 2009

Allowed to use: Calculator, mathematical tables.

All subproblems are given the same weight in the grading.

Problem 1:

A group G of order 12 has the following multiplication table.

| | | | | | | | | | | | | |
|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|-----|
| | e | a | b | c | s | t | u | v | w | x | y | z |
| e | e | a | b | c | s | t | u | v | w | x | y | z |
| a | a | e | c | b | t | s | v | u | x | w | z | y |
| b | b | c | e | a | u | v | s | t | y | z | w | x |
| c | c | b | a | e | v | u | t | s | z | y | x | w |
| s | s | u | v | t | w | y | z | x | e | b | c | a |
| t | t | v | u | s | x | z | y | w | a | c | b | e |
| u | u | s | t | v | y | w | x | z | b | e | a | c |
| v | v | t | s | u | z | x | w | y | c | a | e | b |
| w | w | z | x | y | e | c | a | b | s | v | t | u |
| x | x | y | w | z | a | b | e | c | t | u | s | v |
| y | y | x | z | w | b | a | c | e | u | t | v | s |
| z | z | w | y | x | c | e | b | a | v | s | u | t |

It is generated for example by the three elements a, b, s with the relations $a^2 = b^2 = s^3 = e$, $ab = ba$, $sa = bs$, $sb = cs$, $sc = as$.

- Find subgroups of G .
- Find the conjugation classes.
- If you find a normal (invariant) subgroup H , find also the multiplication table of the quotient group G/H .

d) Find the character table.

Hint: A representation of a quotient group G/H is also representation of G .

The following orthogonality relations hold for a finite group of order N .

Let $\chi_i^{(\mu)}$ be the character value of the conjugation class i , with N_i elements, in the irreducible representation μ . Then

$$\sum_i N_i (\chi_i^{(\mu)})^* \chi_i^{(\nu)} = N \delta_{\mu\nu} ,$$

$$\sum_{\mu} (\chi_i^{(\mu)})^* \chi_j^{(\mu)} = \frac{N}{N_i} \delta_{ij} .$$

e) The group G is the same as A_4 , the alternating group of degree 4, which is the subgroup of even permutations in the symmetric group S_4 . To see this, take for example $a = (12)(34)$, $b = (14)(23)$, $s = (123)(4)$.

A_4 is also the subgroup of proper rotations, excluding reflections, in the symmetry group of a regular tetrahedron, for example a methane (CH_4) molecule.

The orbital angular momentum quantum number $\ell = 0, 1, 2, \dots$ labels the irreducible representations of the full rotation group $\text{SO}(3)$. The dimension of an irreducible representation is $2\ell + 1$, and the character value as a function of the rotation angle α is

$$\chi^{(\ell)}(\alpha) = \frac{\sin((\ell + \frac{1}{2})\alpha)}{\sin(\frac{\alpha}{2})} .$$

An irreducible representation of $\text{SO}(3)$ is in general a reducible representation of the subgroup $A_4 \subset \text{SO}(3)$.

How does the irreducible representation of $\text{SO}(3)$ with $\ell = 2$ split into irreducible representations of A_4 ?

Some formulae that may be useful in the following:

$$[A, BC] = [A, B]C + B[A, C] \quad (\text{the Leibniz rule for commutation})$$

$$e^A B e^{-A} = B + [A, B] + \frac{1}{2} [A, [A, B]] + \cdots + \frac{1}{n!} [A, [A, \cdots [A, B] \cdots]] + \cdots$$

Problem 2:

The Hamiltonian of a one dimensional harmonic oscillator is

$$H = \frac{p^2}{2m} + \frac{1}{2} m\omega^2 x^2,$$

where m is the mass and ω the angular frequency. For simplicity we set $m = 1$, $\omega = 1$, and $\hbar = 1$ (this is a question of choosing a convenient set of units). Then

$$H = \frac{1}{2} (p^2 + x^2) = a^\dagger a + \frac{1}{2},$$

where

$$a = \frac{1}{\sqrt{2}} (x + ip), \quad a^\dagger = \frac{1}{\sqrt{2}} (x - ip). \quad (1)$$

The position x and momentum p are Hermitean linear operators satisfying the canonical commutation relation $[x, p] = i$, or equivalently, $[a, a^\dagger] = 1$.

Let $|\psi\rangle$ be a state vector, normalized so that $\langle\psi|\psi\rangle = 1$. The expectation value of H in the state $|\psi\rangle$ is

$$\langle H \rangle = \langle\psi|H|\psi\rangle = \langle\phi|\phi\rangle + \frac{1}{2},$$

where $|\phi\rangle = a|\psi\rangle$. The ground state $|0\rangle$, in which $\langle H \rangle$ is minimal, is given by the equation

$$a|0\rangle = 0.$$

In the quantization of the electromagnetic field we describe one single mode of the field with angular frequency ω as a one dimensional harmonic oscillator. Then a^\dagger and a are the creation and annihilation operators of photons, and $|0\rangle$ is the vacuum state with no photons in this mode.

a) Define

$$|n\rangle = \frac{1}{\sqrt{n!}} (a^\dagger)^n |0\rangle \quad \text{for } n = 1, 2, \dots$$

Show that $a|n\rangle = \sqrt{n}|n-1\rangle$, and that $N|n\rangle = n|n\rangle$, where $N = a^\dagger a = aa^\dagger - 1$ is the (photon) number operator.

Show also that the state $|n\rangle$ is normalized, $\langle n|n\rangle = 1$.

- b) Let z be an arbitrary complex number, and define a “displacement operator”

$$D = D(z) = e^{za^\dagger - z^*a} .$$

Show that D is unitary, $D^\dagger = D^{-1}$, and that $DaD^{-1} = a - z$.

The operator D transforms the ground state $|0\rangle$ into the state $|z\rangle = D|0\rangle$, which is called a coherent state. Show that the coherent state $|z\rangle$ is an eigenstate with eigenvalue z of the non-Hermitian operator a . That is, $a|z\rangle = z|z\rangle$, or equivalently,

$$(a - z)|z\rangle = 0 .$$

- c) Show that the coherent state can be expanded in terms of the energy eigenstates as

$$|z\rangle = e^{-\frac{|z|^2}{2}} \sum_{n=0}^{\infty} \frac{z^n}{\sqrt{n!}} |n\rangle . \quad (2)$$

It is enough to show that this state solves the eigenvalue equation $a|z\rangle = z|z\rangle$, and that it is normalized.

A different method is to use the Campbell–Baker–Hausdorff formula

$$\exp(A)\exp(B) = \exp\left(A + B + \frac{1}{2}[A, B] + \dots\right) ,$$

where the terms left out are commutators of commutators, in order to compute the product $e^{za^\dagger}e^{-z^*a}$ and thus derive an alternative formula for $D = e^{za^\dagger - z^*a}$.

- d) Assume that the state of the oscillator at time $t = 0$ is the coherent state $|z\rangle$, that $|\psi(0)\rangle = |z\rangle$. Then the state at time t is $|\psi(t)\rangle = U|\psi(0)\rangle = U|z\rangle$, where U is the time development operator,

$$U = U(t) = e^{-itH} .$$

Show that $U|z\rangle = e^{-\frac{it}{2}} |e^{-it}z\rangle$.

Thus, a coherent state remains a coherent state as it develops in time.

Again there are at least two possible ways to solve the problem. We may either use directly equation (2), or we may compute

$$UD = UDU^{-1}U = e^{zUa^\dagger U^{-1} - z^*UaU^{-1}}U .$$

- e) The variance of x in a state $|\psi\rangle$ is defined as

$$(\Delta x)^2 = \langle\psi|(x - \langle x\rangle)^2|\psi\rangle = \langle(x - \langle x\rangle)^2\rangle = \langle x^2\rangle - \langle x\rangle^2 .$$

The variance of p is defined in a similar way. The Heisenberg uncertainty relation

$$\Delta x \Delta p \geq \frac{1}{2}$$

may be proved as follows. Define

$$b = x + i\lambda p , \quad b^\dagger = x - i\lambda p ,$$

with λ as a real parameter, and define also

$$w = \langle \psi | b | \psi \rangle = \langle b \rangle = \langle x \rangle + i\lambda \langle p \rangle .$$

Since

$$\begin{aligned} (b^\dagger - w^*)(b - w) &= (x - \langle x \rangle)^2 + \lambda^2 (p - \langle p \rangle)^2 + i\lambda [x - \langle x \rangle, p - \langle p \rangle] \\ &= (x - \langle x \rangle)^2 + \lambda^2 (p - \langle p \rangle)^2 - \lambda , \end{aligned}$$

we may define $|\phi\rangle = (b - w)|\psi\rangle$ and deduce that

$$\begin{aligned} 0 \leq \langle \phi | \phi \rangle &= \langle \psi | (b^\dagger - w^*)(b - w) | \psi \rangle = (\Delta x)^2 + \lambda^2 (\Delta p)^2 - \lambda \\ &= (\Delta x)^2 + \left(\lambda \Delta p - \frac{1}{2\Delta p} \right)^2 - \frac{1}{4(\Delta p)^2} . \end{aligned}$$

Given the state $|\psi\rangle$, the inequality must hold for an arbitrary value of λ . In particular, with $\lambda = 1/(2(\Delta p)^2)$ we obtain the Heisenberg uncertainty relation.

We say that $|\psi\rangle$ is a *minimum uncertainty state* if $\Delta x \Delta p = 1/2$. A minimum uncertainty quantum state is the best possible approximation to a classical state.

In the notation used above, if $|\psi\rangle$ is a minimum uncertainty state we have that

$$\langle \phi | \phi \rangle = \left(\lambda \Delta p - \frac{1}{2\Delta p} \right)^2 .$$

Hence, if we choose $\lambda = 1/(2(\Delta p)^2)$ we must have that $|\phi\rangle = (b - w)|\psi\rangle = 0$.

We see that a minimum uncertainty state $|\psi\rangle = |\lambda, w\rangle$ is characterized by a real parameter λ and a complex parameter w , and it is an eigenvector of the non-Hermitian operator $b = x + i\lambda p$ with w as eigenvalue,

$$b |\lambda, w\rangle = w |\lambda, w\rangle .$$

The expectation values and variances of x and p in this state are given by the formulae

$$\langle x \rangle + i\lambda \langle p \rangle = w , \quad \Delta x = \sqrt{\frac{\lambda}{2}} , \quad \Delta p = \frac{1}{\sqrt{2\lambda}} .$$

A coherent state is a minimum uncertainty state with $\lambda = 1$. A minimum uncertainty state with $\lambda \neq 1$ is called a *squeezed state*, because it has smaller uncertainty for either x or p than a coherent state.

The squeezed state corresponding to the ground state $|0\rangle$ (the “squeezed vacuum”) is the state $|\lambda, 0\rangle$ with $w = 0$, defined by the equation

$$b |\lambda, 0\rangle = (x + i\lambda p) |\lambda, 0\rangle = 0 .$$

Compute UbU^{-1} where $U = e^{-itH}$ is the time development operator.

What can you say from this about the time development of the squeezed vacuum state $|\lambda, 0\rangle$?
